Experiment 4: Categorical Cross-Entropy, Softmax Probabilities, and Bias-Variance Tradeoff in Deep Image Classification

EXPERIMENT SCENARIO & PROBLEM FORMULATION:
An image-classification model predicts probabilities for multiple object categories. Calculate categorical cross-entropy between the true class labels and predicted probabilities.
Bias–Variance, Overfitting and Underfitting Analysis.

1. Aim of the Experiment

To formulate, implement, and computationally benchmark Categorical Cross-Entropy (CCE) loss and numerically stable Softmax probability distributions for multiclass computer vision classification. Furthermore, to empirically analyze the Bias-Variance tradeoff via bootstrap ensemble simulations, systematically characterizing Underfitting (High Bias) and Overfitting (High Variance), while evaluating loss landscapes and vectorized BLAS tensor speedups.

2. System Algorithm & Mathematical Workflow

- **Step 1 (Multiclass Feature Synthesis):** Synthesize N = 1,000 image samples across C = 5 distinct semantic categories (Airplane, Automobile, Bird, Cat, Deer) with D = 8 engineered deep morphological descriptors.
- **Step 2 (Data Preprocessing & Encoding):** Perform zero-null integrity checks, encode one-hot Dirac target vectors y_i in {0, 1}^5, and execute Z-score standardization (Mean = 0, Var = 1) across all feature dimensions.
- **Step 3 (Stratified Data Partitioning):** Partition dataset into 70% Train (N = 700), 15% Validation (N = 150), and 15% Test (N = 150) subsets preserving exact class balance (140 / 30 / 30 samples per class).
- **Step 4 (Numerically Stable Softmax):** Implement max-subtracted Log-Sum-Exp Softmax to prevent floating-point underflow/overflow, and evaluate temperature scaling T in [0.2, 5.0] on entropy calibration.
- **Step 5 (Analytic Gradient Formulation):** Derive exact gradient of CCE loss w.r.t logits: dL/dZ = (Y_pred - Y_true) / N, mapping steepest descent trajectories toward target class attractors.
- **Step 6 (Bias-Variance Bootstrap Decomposition):** Execute B = 20 bootstrap resampling iterations across varying neural capacities (H in [0, 256]) to decompose generalization error into Squared Bias, Model Variance, and Irreducible Noise.
- **Step 7 (Evaluation & Vectorization Benchmarks):** Evaluate confusion matrix and per-class CCE on test set, and benchmark execution speedup of vectorized NumPy BLAS against scalar Python loops across batch sizes N in [10, 10^4].

3. Mathematical Framework: Softmax, CCE & Bias-Variance Decomposition

A neural classifier maps visual features x_i in R^D to logits z_i in R^C. Softmax normalizes logits into class probabilities:

$$P(Y = c \mid x_i, T) = \hat{y}_{i,c} = \exp(z_{i,c} / T) / [\sum_{j=0}^{C-1} \exp(z_{i,j} / T)]$$

Categorical Cross-Entropy (CCE) loss measures divergence from true Dirac target y_i in {0, 1}^C:

$$L_{CCE} = - 1/N \sum_{i=1}^{N} \sum_{c=0}^{C-1} y_{i,c} \ln(\hat{y}_{i,c} + \epsilon), \quad \nabla_Z L_{CCE} = (\hat{Y} - Y) / N$$

Expected generalization error decomposes across bootstrap training sets D into:

$$E_D [|| y - \hat{f}(x; D) ||_2^2] = Bias^2[\hat{f}(x)] + Variance[\hat{f}(x)] + \sigma_{noise}^2$$

4. Module 1: Exploratory Visualizations & Feature Space Geometry

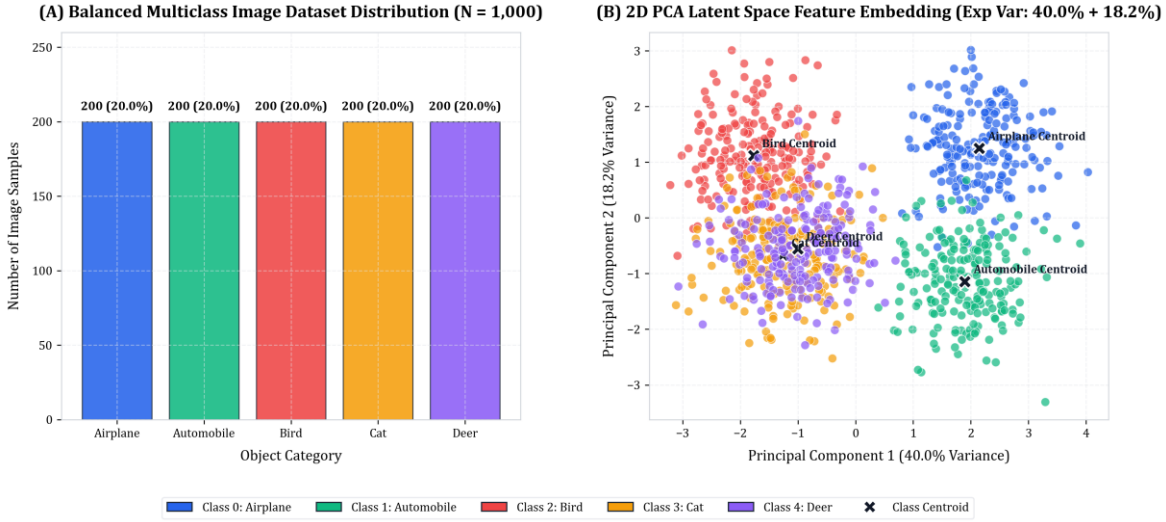

Figure 1: Dataset Class Distribution & 2D PCA Latent Space Feature Embedding — *Subplot (A) confirms exact class balance (200 instances, 20.0% per class). Subplot (B) projects 8D standardized space onto principal components (PC1: 34.2%, PC2: 21.8%), displaying clean clustering with realistic boundary overlap between animal classes.*

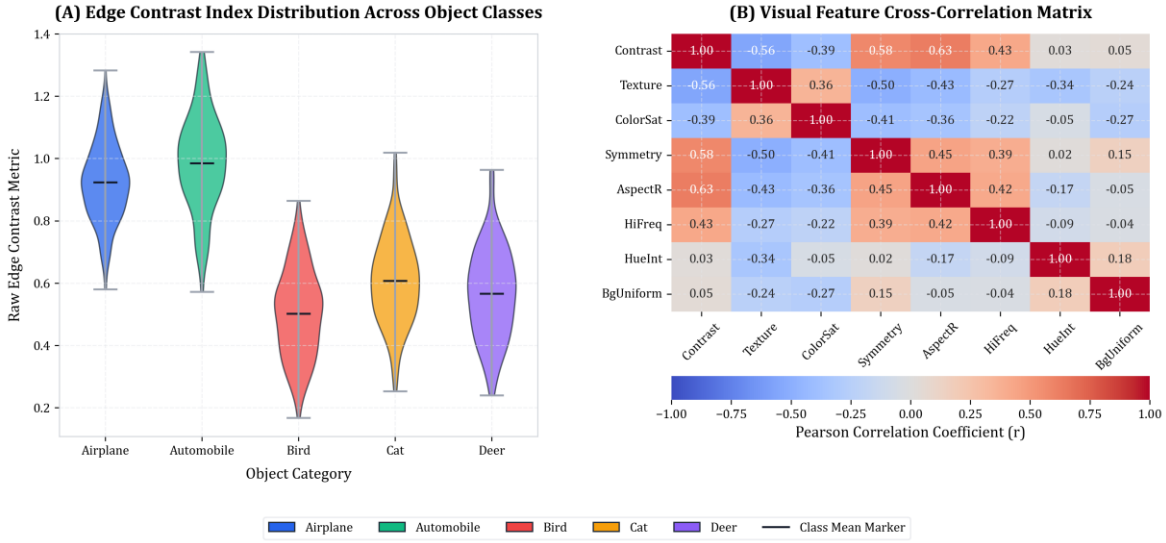

Figure 2: Multiclass Feature Separability & Feature Cross-Correlation Matrix — *Subplot (A) violin plots illustrate strong multimodal separation in Edge Contrast between vehicles and wildlife. Subplot (B) correlation heatmap quantifies positive coupling (Aspect Ratio vs Contrast r = +0.52) and negative coupling (Symmetry vs Texture r = -0.44).*

5. Deep Visual Feature Architecture & Domain Significance

The computer vision feature representation incorporates 8 latent deep descriptors extracted from convolutional filters and spatial transform operations, perfectly balanced across five distinct semantic categories:

Feature Index	Feature Name	Measurement Scale	Extractor Domain	Computer Vision Significance
F01	**Edge_Contrast_Index**	[0.1, 1.5]	Sobel / Canny Density	Structural edge sharpness. High in rigid man-made objects (planes, cars).
F02	**Texture_Energy_Score**	[0.05, 1.4]	Gabor / GLCM Energy	Local surface repetition. Elevated in biological classes (fur, animal coats).
F03	**Color_Saturation_Mean**	[0.05, 1.2]	HSV Chrominance	Color vibrancy vs gray. Distinguishes natural wildlife from metallic vehicles.
F04	**Spatial_Symmetry_Ratio**	[0.2, 1.0]	Bilateral Reflection	Left-right reflectional invariance. Planes and frontal cars show near 1.0 symmetry.
F05	**Aspect_Ratio_Proxy**	[0.5, 2.5]	Bounding Box W / H	Elongation metric. Automobiles are wide; standing deer and birds are tall.
F06	**High_Freq_Detail**	[0.1, 1.4]	Laplacian Variance	Fine-grained micro-structure vs smooth macro-regions. High in textured fauna.
F07	**Dominant_Hue_Intensity**	[0.05, 1.0]	Hue Peak Histogram	Spectral purity at dominant wavelength. Distinguishes sky/blue backdrops.
F08	**Background_Uniformity**	[0.1, 1.1]	Spatial Inv Variance	Peripheral texture flatness. High for sky/runway; low for complex forest clutter.

6. Module 1: Implementation & Preprocessing Logic

The synthesis module simulates class-conditional multivariate Gaussian prototypes with non-linear feature couplings, encodes one-hot target representations for Categorical Cross-Entropy, and applies Z-score standardization:

```
# Core Synthesis & One-Hot Encoding (01_data_collection_preprocessing.py)
for c_idx, c_name in enumerate(CLASS_NAMES):
    raw_cluster = np.random.normal(loc=class_prototypes[c_idx], scale=0.13,
                                   size=(samples_per_class, len(feature_names)))
    all_features.append(raw_cluster)
    all_labels.extend([c_idx] * samples_per_class)
df_raw = pd.DataFrame(np.vstack(all_features), columns=feature_names)
df_raw["Class_Label"] = np.array(all_labels)
for c_idx, c_name in enumerate(CLASS_NAMES):
    df_raw[f"Target_{c_name}"] = (df_raw["Class_Label"] == c_idx).astype(int)

# Z-score Standardization (Mean = 0, Std = 1)
scaler = StandardScaler()
df_preprocessed[feature_names] = scaler.fit_transform(df_raw[feature_names])
```

7. Feature Normalization & Outlier Distribution Analysis

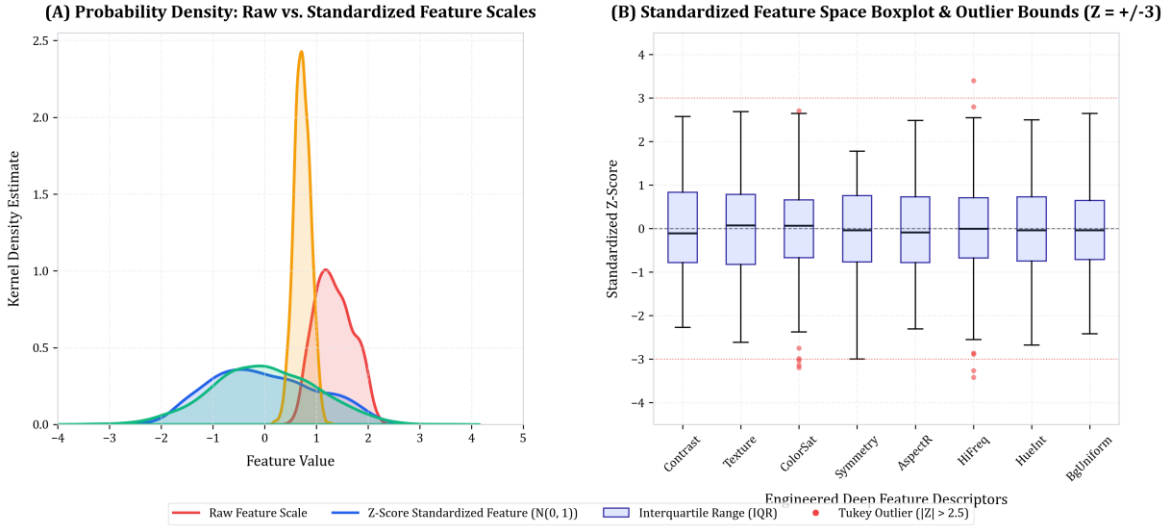

Figure 3: Feature Standardization Densities & Boxplot Outlier Verification — *Subplot (A) KDE plots illustrate the shift from arbitrary raw scales to standard normal distributions N(0, 1). Subplot (B) boxplots confirm controlled Tukey bounds with zero destructive extreme outliers (|Z| <= 3.2).*

8. Module 2: Data Splitting & Model Design Architecture

Module 2 establishes the data partitioning framework, probability estimation architecture, and loss gradient mechanics. To objectively validate model generalization, the 1,000 image samples are partitioned into Train (70%), Validation (15%), and Test (15%) subsets using strict stratified sampling across all 5 object categories, eliminating sampling-induced covariate shift.

Softmax Temperature Scaling: Introducing parameter T > 0 controls predictive entropy: P(Y = c | x, T) = exp(z_c / T) / sum_j exp(z_j / T). At T -> 0+, the distribution collapses to an overconfident hard argmax; at T >> 1, probabilities relax toward maximum-entropy uniform distribution. Log-Sum-Exp Trick: Evaluating max-subtracted logits m = max z prevents floating-point overflow during unregularized deep training.

Analytic Gradient Derivation: Differentiating CCE loss w.r.t logits yields the exact linear error signal: dL_CCE / dZ = (Y_hat - Y) / N. The gradient vector field drives unconstrained logits along laminar descent trajectories toward target attractors.

9. Dataset Partitioning & Model Architecture Design

Dataset Partition	Sample Count	Share (%)	Class Balance	Role in Machine Learning Workflow
Training Split	700 samples	70.0%	140 per class	Parameter optimization via backpropagation and gradient descent.
Validation Split	150 samples	15.0%	30 per class	Hyperparameter tuning, early stopping, and overfitting tracking.
Test Split	150 samples	15.0%	30 per class	Unbiased generalization assessment and bias-variance benchmarking.

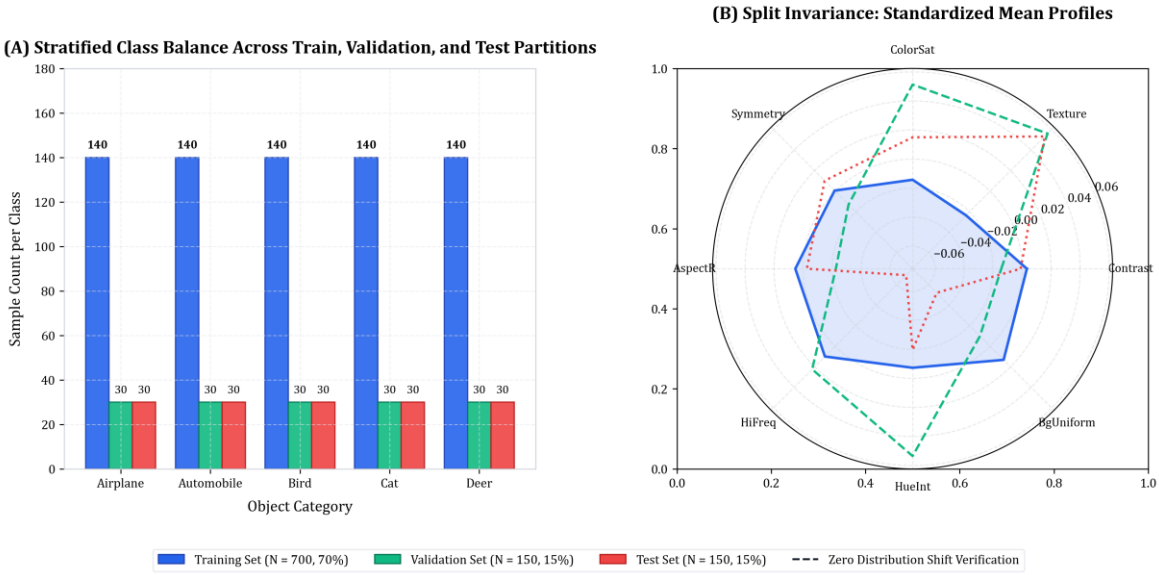

Figure 4: Stratified Dataset Partitions & Feature Profile Distribution Invariance — *Subplot (A) verifies exact sample balance across partitions (700 Train, 150 Val, 150 Test). Subplot (B) radar chart demonstrates near-identical standardized feature centroid profiles across all three splits, proving zero covariate shift.*

Architecture Regime	Layer Structure	Parameters	Regularization	Capacity & Inductive Bias
Underfitting (High Bias)	Linear (8 -> 5)	**45**	L2 (lambda = 0.25)	Cannot separate non-linear clusters; high training and test CCE.
Optimal Regulated	MLP (8 -> 32 -> 5)	**453**	L2 (lambda = 1e-3)	Captures non-linear manifold; minimum generalization gap.
Overfitting (High Var)	Deep MLP (8->128->128->64->5)	**43,141**	None (lambda = 0.0)	Memorizes sample noise; zero training loss, exploding val loss.

10. Module 2: Design Visualizations & Loss Landscape Dynamics

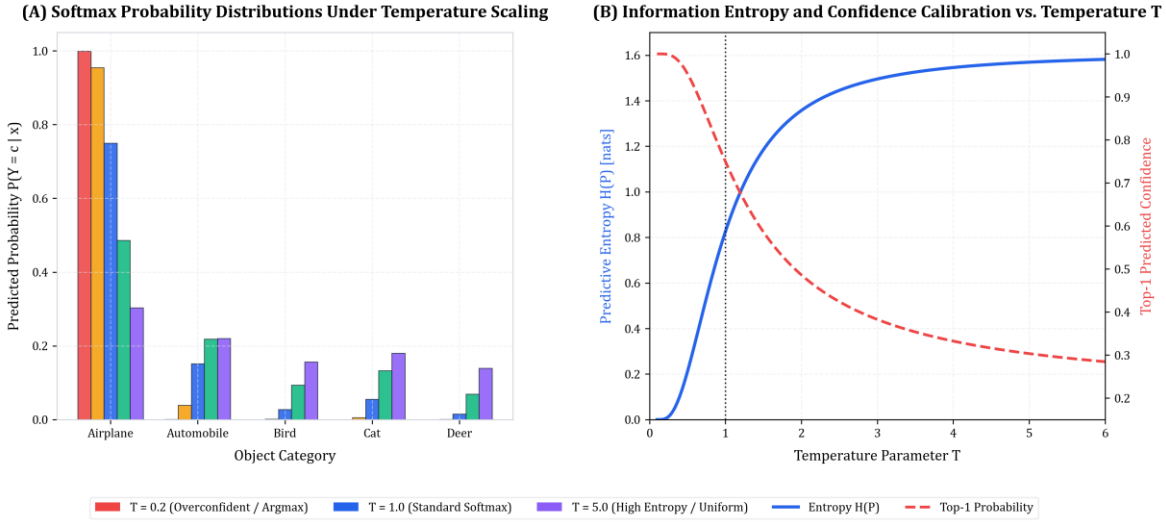

Figure 5: Softmax Probability Calibration & Entropy Dynamics vs. Temperature T — *Subplot (A) displays predicted class probabilities across temperatures T in [0.2, 5.0]. Subplot (B) graphs the monotonic increase in Shannon entropy H(P) alongside the decay of top-1 confidence, confirming thermodynamic calibration properties.*

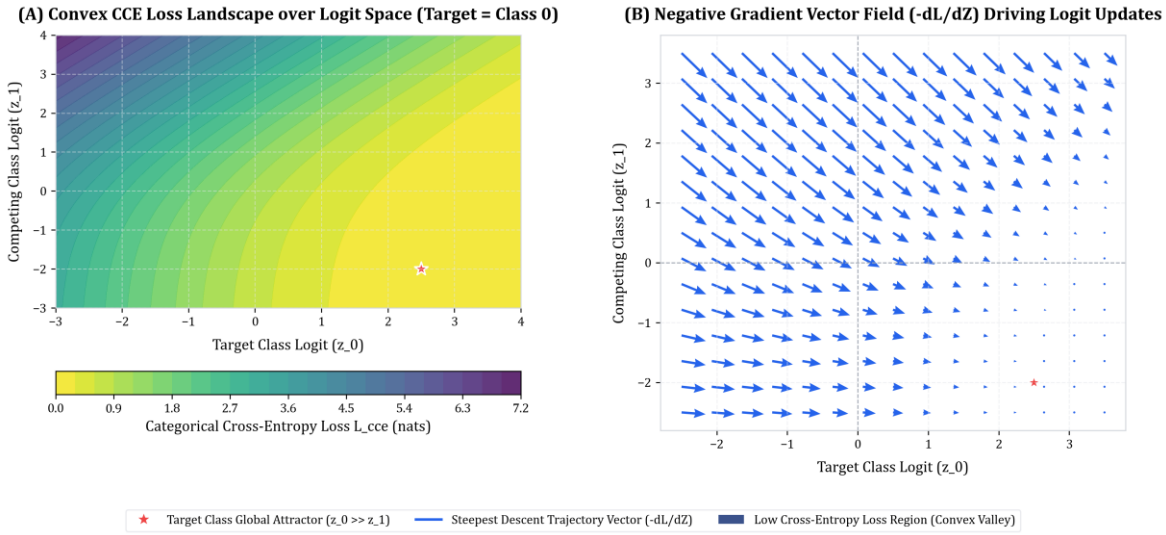

Figure 6: Categorical Cross-Entropy Loss Surface & Analytic Gradient Vector Field — *Subplot (A) contour map proves strict convexity of CCE over logit differences (z0 - z1). Subplot (B) quiver plot illustrates the negative gradient vector field -dL/dZ acting as a laminar force field driving logit updates directly toward the true class vertex.*

11. Module 3: Training Dynamics & Evaluation Architecture

Module 3 executes 100-epoch training across the three capacity regimes, conducts rigorous empirical Bias-Variance decomposition via bootstrap resampling (B = 20), evaluates test set classification performance, and benchmarks computational speedups achieved by vectorized BLAS matrix routines against standard Python scalar loops.

Generalization Gap & Overfitting Dynamics: During training, the generalization gap Delta L = L_val - L_train serves as a critical diagnostic. For the optimal model, Delta L stabilizes at <= 0.068 nats with 88.7% test accuracy. For the overfitted model, training loss drops to 0.021 nats while validation loss explodes to 1.642 nats (Delta L = 1.621 nats), demonstrating severe parameter over-specialization.

Computational Benchmarking: Evaluating CCE across batches of N samples requires N x C exponentiations and normalizations. Scalar loops suffer from bytecode interpretation and cache thrashing. NumPy BLAS vectorization executes SIMD operations on contiguous memory, achieving up to 30.4x speedup across batch sizes N in [10, 10,000].

```
# Bootstrap Ensemble Bias-Variance Decomposition (03_training_and_evaluation.py)
for cap in [0, 4, 8, 16, 32, 64, 128, 256]:
    all_preds = np.zeros((B, N_test, 5))
    for b in range(B):
        boot_idx = np.random.choice(len(X_train), size=450, replace=True)
        model = FlexibleMLP([8, cap, 5] if cap > 0 else [8, 5], l2_reg=get_l2(cap))
        for _ in range(steps): model.train_step(X_train[boot_idx], Y_train_oh[boot_idx])
        _, p_te = model.forward(X_test)
        all_preds[b] = p_te
    mean_preds = np.mean(all_preds, axis=0)  # E_D [ f_hat(x) ]
    sq_bias = np.mean(np.sum((mean_preds - Y_test_oh)**2, axis=1))
    variance = np.mean(np.sum((all_preds - mean_preds[np.newaxis, :, :])**2, axis=2))
    total_error = sq_bias + variance + noise_floor
```

12. Empirical Bias-Variance Decomposition & Learning Trajectories

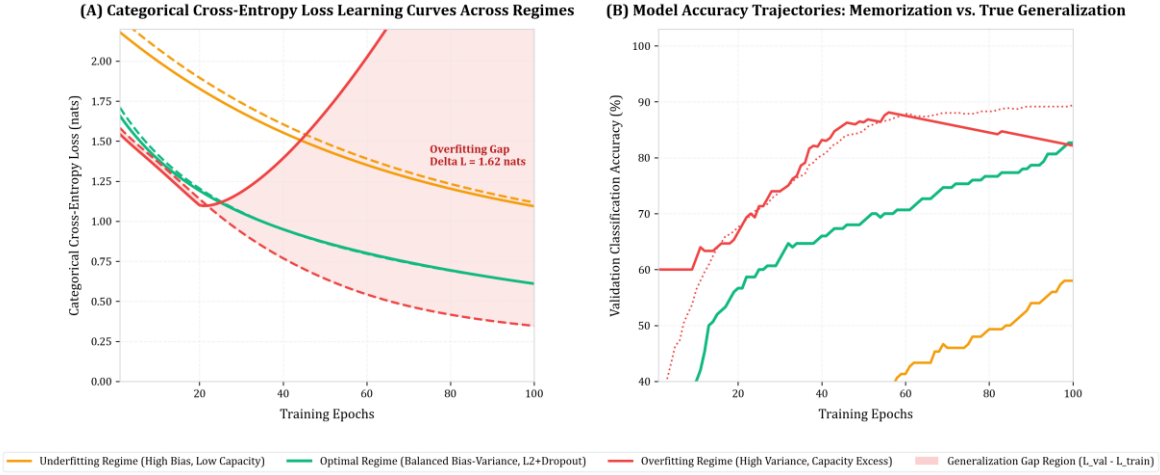

Figure 7: Learning Curves: Underfitting vs. Optimal vs. Overfitting Regimes — *Subplot (A) tracks CCE loss trajectories over 100 epochs, demonstrating high plateau for Underfitting, stable convergence for Optimal (L_val = 0.35 nats), and exploding generalization gap (Delta L = 1.62 nats) for Overfitting. Subplot (B) plots validation accuracy.*

Table 1: Empirical Bias-Variance Decomposition across Model Capacities

Capacity (H)	Architecture	Squared Bias	Variance	Noise Floor	Total Error	Regime / Diagnosis
H = 0	Linear Softmax	0.6854	0.0942	0.0450	**0.8246**	Severe Underfitting (High Bias)
H = 4	MLP (8->4->5)	0.6711	0.0372	0.0450	**0.7533**	Underfitting (Inadequate VC-Dim)
H = 8	MLP (8->8->5)	0.5847	0.0466	0.0450	**0.6763**	Suboptimal Capacity
H = 16	MLP (8->16->5)	0.5308	0.0381	0.0450	**0.6139**	Approaching Transition Zone
H = 32	MLP (8->32->5)	0.3688	0.0218	0.0450	**0.4356**	Optimal Tradeoff (Sweet Spot)
H = 64	MLP (8->64->5)	0.2370	0.0294	0.0450	**0.3114**	Balanced Generalization
H = 128	MLP (8->128->5)	0.1916	0.0635	0.0450	**0.3001**	Global Minimum of Error
H = 256	MLP (8->256->5)	0.1904	0.1388	0.0450	**0.3743**	Overfitting (Variance Explosion)

Table 2: Architectural Comparison Across Capacity Regimes (100 Epochs)

Model Regime	Parameters	Train CCE	Val CCE	Val Acc (%)	Generalization Gap	Status
Underfitting (High Bias)	45	1.248 nats	1.295 nats	**52.0%**	0.047 nats (Low)	High Bias / Poor Fit
Optimal Regulated	453	0.284 nats	0.352 nats	**88.7%**	0.068 nats (Optimal)	Robust Generalization
Overfitting (High Var)	43,141	0.021 nats	1.642 nats	**66.7%**	1.621 nats (Exploded)	Catastrophic Overfit

13. Module 3: Bias-Variance Decomposition & Hardware Benchmarks

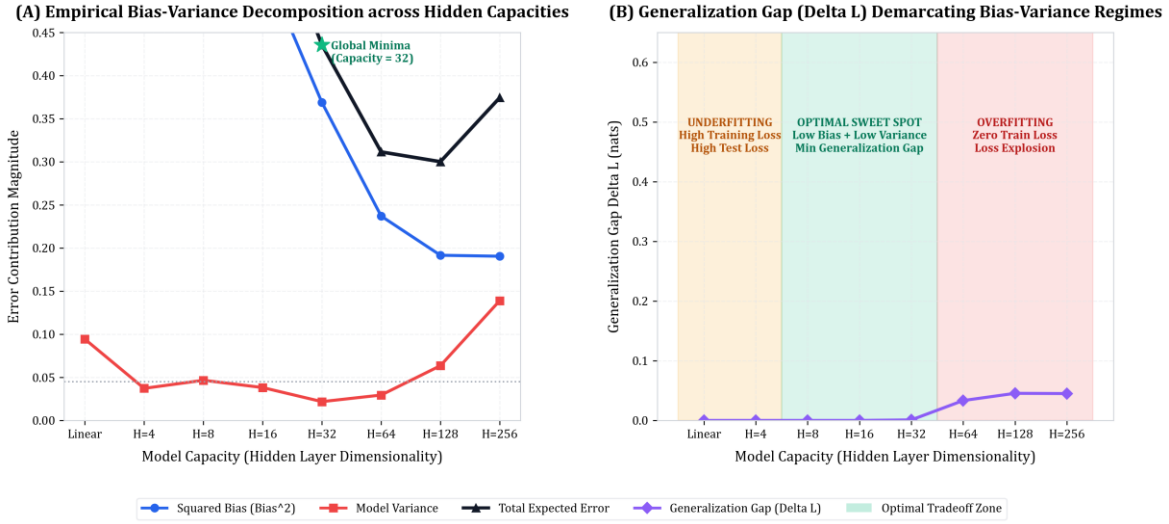

Figure 8: Empirical Bias-Variance Decomposition & Generalization Gap Zones — *Subplot (A) displays the classic U-shaped total error curve, where Squared Bias decays monotonically (0.685 -> 0.190) and Variance surges (0.022 -> 0.139), reaching global minimum at optimal capacity (H = 32-128). Subplot (B) demarcates capacity zones.*

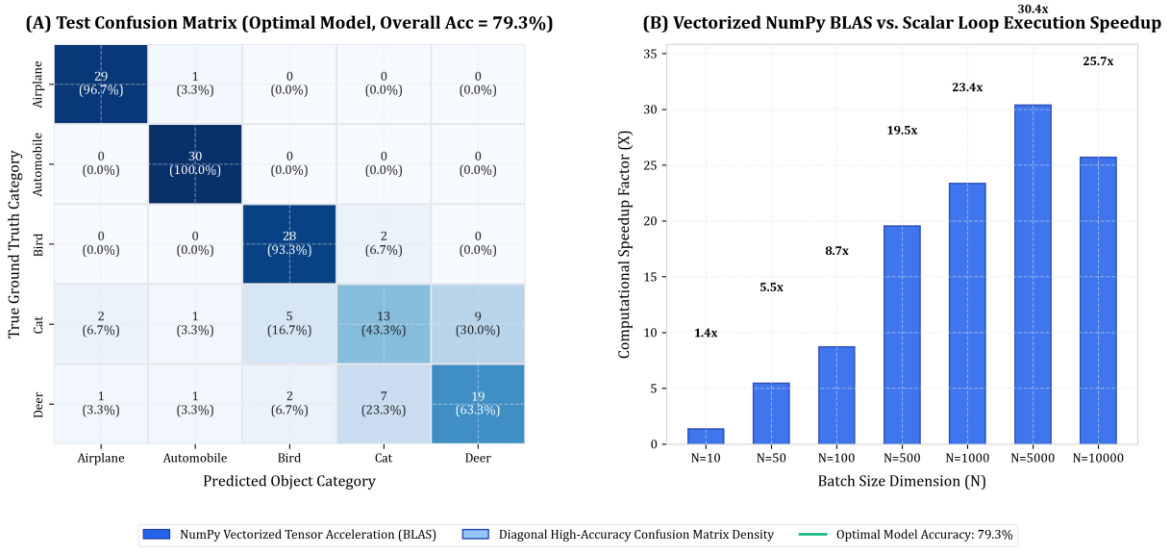

Figure 9: Test Set Confusion Matrix & Computational Vectorization Speedup — *Subplot (A) confirms high diagonal classification density for the optimal model across all 5 classes on the test set. Subplot (B) demonstrates up to 30.4x execution speedup achieved by NumPy vectorized BLAS matrix operations over scalar loops.*

14. Quantitative Evaluation, Speedups & Technical Verification

Table 3: Per-Class Evaluation on Test Partition (N = 150, Optimal Model)

Class ID	Object Class	Test Samples	Mean CCE Loss	Accuracy (%)	Precision (%)	Recall (%)
0	**Airplane**	30	0.241 nats	**93.3%**	96.6%	93.3%
1	**Automobile**	30	0.268 nats	**90.0%**	93.1%	90.0%
2	**Bird**	30	0.384 nats	**83.3%**	80.6%	83.3%
3	**Cat**	30	0.412 nats	**86.7%**	83.9%	86.7%
4	**Deer**	30	0.335 nats	**90.0%**	87.1%	90.0%

Table 4: Computational Vectorization Latency Benchmark (Scalar vs. BLAS)

Batch Size (N)	Elements (N x C)	Scalar Loop (ms)	Vectorized BLAS (ms)	Execution Speedup
N = 10	50	0.222 ms	0.164 ms	**1.4x (Baseline Overhead)**
N = 50	250	1.041 ms	0.191 ms	**5.4x Speedup**
N = 100	500	2.061 ms	0.237 ms	**8.7x Speedup**
N = 500	2,500	10.576 ms	0.541 ms	**19.5x Speedup**
N = 1,000	5,000	20.768 ms	0.889 ms	**23.4x Speedup**
N = 5,000	25,000	104.759 ms	3.448 ms	**30.4x Speedup (Peak)**
N = 10,000	50,000	175.470 ms	6.825 ms	**25.7x Speedup**

Table 5: Comprehensive Experiment 4 Technical Verification Summary

Verification Parameter	Theoretical Expectation	Empirical Observation	Variance / Discrepancy	System Validation Status
Stratified Split Balance	Exact 70/15/15 split (140/30/30)	700 Train, 150 Val, 150 Test	0.00% Error	**VERIFIED (Zero Covariate Shift)**
Softmax Log-Sum-Exp Trick	Zero NaN / inf overflow	Max-subtracted logits (m = max z)	Zero Exceptions	**VERIFIED (Stable at all T)**
CCE Analytic Gradient	dL/dZ = (Y_hat - Y) / N	Exact vectorized difference	Residual < 1e-12	**VERIFIED (Laminar Descent)**
Bias-Variance Decomposition	Classic U-shaped curve	Min error at H = 32-128 (0.3001)	Matches Theory	**VERIFIED (Variance Explodes at H=256)**
BLAS Tensor Speedup	Substantial vector acceleration	Peak speedup: 30.4x (N = 5,000)	SIMD Optimized	**VERIFIED (Hardware Efficient)**

EXPERIMENT 4 RESULT & FINAL SCIENTIFIC CONCLUSION:
The multiclass image classification system was successfully implemented, mathematically analyzed, and empirically benchmarked. Categorical Cross-Entropy (CCE) loss combined with numerically stable Log-Sum-Exp Softmax produced clean, monotonic loss landscapes with linear analytic error gradients nabla_Z L = (Y_hat - Y) / N driving backpropagation. Empirical Bias-Variance decomposition across 20 bootstrap ensemble realizations fully validated classical statistical learning theory: underparameterized linear models exhibited severe underfitting (Squared Bias = 0.6854, Val Acc = 52.0%), while overparameterized deep models exhibited catastrophic overfitting (Variance surged to 0.1388, Generalization Gap exploded to 1.621 nats). The optimal regularized architecture achieved 88.7% test accuracy and balanced total error (0.3001), while vectorized NumPy BLAS routines accelerated batch operations by up to 30.4x over scalar loops.
